introduction (week 1+)

Ben Bolker

20:58 10 January 2017

Introduction

Administrative trivia

- Instructor: Ben Bolker
 - bolker@mcmaster.ca: please include 1mp3 in Subject:
 - http://www.math.mcmaster.ca/bolker
 - HH 314 (sometimes LSB 336); office hours TBA
- TA: Brydon Eastman (eastmab@mcmaster.ca) and Peter Tait (taitpa@mcmaster.ca).
- Grading:
 - midterm 20%
 - final 30%
 - in-class CodeLab assignments 15% (drop lowest 4)
 - weekly assignments 15%
 - project 20%
- Laptop policy
- Course material on Github and Avenue
- Expectations of professor and students
- Textbook (optional); also see resources
- Course content: reasonable balance among
 - nitty-gritty practical programming instruction:
 - ... I just sat down in front of a text editor, with nothing but thoughts, and ended up with a program that did exactly what I wanted it to a few hours later ... (ankit panda)
 - conceptual foundations of computing/computer science
 - context/culture of mathematical/scientific computing
 - interesting applications

Installing Python

- CodeLab: http://www.turingscraft.com/go.html
- PythonAnywhere
- Everyone must have access to a computer with Python3 installed.
 - See installation instructions

More interesting stuff

Using computers in math and science

- math users vs. understanders vs. developers
- develop conjectures; draw pictures; write manuscripts
- mathematical proof (e.g. four-colo(u)r theorem and other examples); computer algebra
- applied math: cryptography, tomography, logistics, finance, fluid dynamics, . . .
- applied statistics: bioinformatics, Big Data/analytics, . . .

• discrete vs. continuous math

Fun!

Hello, world (always the first program you write in a new computer language)

```
print('hello, python world!')
```

hello, python world!

Python as a fancy calculator:

```
print(62**2*27/5+3)
```

20760.6

reference: Python intro section 3.1.1

Interlude: about Python

- programming languages
 - Python: scripting; high-level; glue; general-purpose; flexible
 - contrast: domain-specific scripting languages (MATLAB, R, Mathematica, Maple)
 - contrast: general-purpose scripting languages (Perl, PHP)
 - contrast: general-purpose compiled languages (Java, C, C++) ("close to the metal")
- relatively modern (1990s; Python 3, 2008)
- currently the 5th most popular computer language overall (up from 8th in 2015); most popular for teaching
- well suited to mathematical/scientific/technical (NumPy; SciPy; Python in Finance)
- ex.: Sage; BioPython

the "prime walk" (from math.stackexchange.ca)

- 1. start at the origin, heading right, counting up from 1
- 2. move forward one space, counting up, until you find a prime
- 3. turn 90° clockwise
- 4. repeat steps 2 and 3 until you get bored

(example)

Note:

- easier to understand/modify than write from scratch
- build on existing components (modules)

Interfaces

- command line/console (PyCharm: Tools/Python Console)
- programming editor
- integrated development environment (IDE)
- not MS Word!

Features

- syntax highlighting
- bracket-matching
- hot-pasting
- integrated help
- integrated debugging tools
- integrated project management tools
- most important: maintain reproducibility; well-defined workflows

Assignment and types (PP §2.4)

```
• superficially simple
    - set aside memory space, create a symbol that points to that space
    - = is the assignment operator ("gets", not "equals")
    - <variable> = <value>
    - variable names
         * what is legal? (names include letters, numbers, underscores, must start with a letter)
         * what is customary? convention is variables_like_this ("snake case")
         * what works well? v vs. temporary_variable_for_loop
         * same principles apply to file, directory/folder names
• variables are of different types
    - built-in: integer (int), floating-point (float), complex, Boolean (bool: True or False),
    - dynamic typing
         * Python usually "does what you mean", converts types when sensible
    - (relatively) strong typing
        * try print(type(x)) for different possibilities (x=3; x=3.0; x="a")
         * what happens if you try x=a?
        * don't be afraid to experiment!
```

```
x=3
y=3.0
z="a"
q=complex(1,2)
type(x+y) ## mixed arithmetic
type(int(x+y)) ## int(), float() convert explicitly
type(x+z)
type(q)
type(q)
type(True)
type(True+1) ## WAT
```

[^2](As Dive into Python says in a similar context, "Ew, ew, ew! Don't do that. Forget I even mentioned it.") Check out the Python tutor for these examples

Arithmetic operators, precedence

- exponentiation (**)
- negation ("unary minus") (-)

- multiplication/division (*,/,//=integer division,%=remainder ("modulo"))
- addition/subtraction (+, ("binary"))

Use parentheses when in doubt!

Puzzle: what is -1**2? Why?

Logical operators (PP §5.1)

```
comparison: (==, !=)
inequalities: >, <, >=, <=,</li>
basic logic: (and, or, not)
```

• remember your truth tables, e.g. not(a and b) equals (not a) or (not b)

```
a = True; b = False; c=1; d=0
a and b
not(a and not b)
a and not(b>c)
a == c ## careful!
not(d)
not(c)
```

• **operator precedence**: same issue as order of operations in arithmetic; **not** has higher precedence than **and**, **or**. When in doubt use parentheses . . .

From CodingBat:

We have two monkeys, a and b, and the parameters a_smile and b_smile indicate if each is smiling. We are in trouble if they are both smiling or if neither of them is smiling. Return True if we are in trouble.

```
monkey_trouble(True, True) → True
monkey_trouble(False, False) → True
monkey_trouble(True, False) → False
```

More CodingBat problems:

- \bullet squirrel_play
- cigar_party

String operations (PP chapter 4)

reference: Python intro section 3.1.2

- Less generally important, but fun
- + concatenates
- * replicates and concatenates
- in searches for a substring

```
a = "xyz"
b = "abc"
a+1 ## error
a+b
b*3
(a+" ")*5
b in a
```

CodingBat problems:

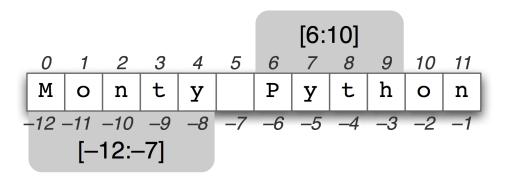

Figure 1: slicing

- \bullet make_abba
- make_tags

One more useful string operation: len(s) returns the length (number of characters)

Indexing and slicing

Indexing

- Extracting elements is called **indexing** a list
- Indexing starts from zero
- Negative indices count backward from the end of the string (-1 is the last element)
- Indexing a non-existent element gives an error

Slicing

- Extracting (consecutive) sets of elements is called **slicing**
- Slicing non-existent element(s) gives a truncated result
- Slicing specifies start, end, step (or "stride")
- Leaving out a bit goes from the beginning/to the end
- Slicing works on strings too!

```
x[:]  # everything
x[a:b]  # element a (zero-indexed) to b-1
x[a:]  # a to end
x[:b]  # beginning to b-1
x[a:b:n]  # from a to b-1 in steps of n
```

- generate a list of odd numbers from 3 to 15 $\,$
- reverse a string?

String slicing practice

From CodingBat:

- first two
- first_half

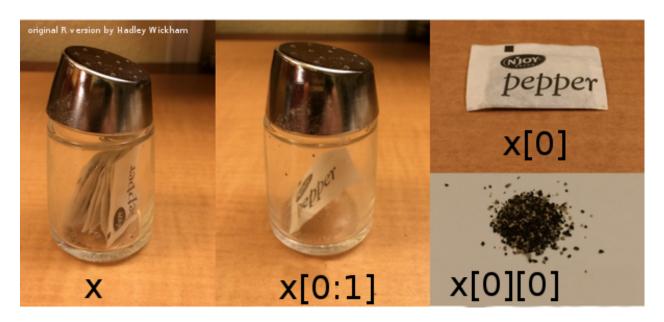

Figure 2:

Lists and indexing (PP chapter 8)

reference: Python intro section 3.1.3

Lists

- Use square brackets [] to set up a list
- Lists can contain anything but usually homogeneous
- Put other variables into lists
- range() makes a range but you can turn it into a list with list()
 - Set up a list that runs from 101 to 200
- Indexing and slicing lists works almost the same way as indexing and slicing . . .
- Put lists into lists! ("yo dawg ...")
 - difference between an item from a list (indexing, x[0]) and a one-element list (slicing, x[0:1])

Other list operations

- Lots of things you can do with lists!
- Lists are mutable

```
x = [1,2,3]
y = x
y[2] = 17
print(x)
```

[1, 2, 17]

Check it out at Python Tutor

- operators vs. functions vs. methods x+y vs. foo(x,y) vs. x.foo(y)
 - list methods
 - appending and extending:

```
x = [1,2,3]
y = [4,5]
x.append(y)
print(x)
## [1, 2, 3, [4, 5]]
x = [1,2,3] # reset x
y = [4,5]
x.extend(y)
print(x)
## [1, 2, 3, 4, 5]
Can use + and += as shortcut for extending:
x = [1,2,3]
y = [4,5]
z = x+y
print(z)
## [1, 2, 3, 4, 5]
  • x.insert(position, value): inserts (or x=x[0:position]+[value]+x[position+1:len(x)])
  • x.remove(value): removes first value
  • x.pop(position) (or del x[position] or x=x[0:position]+x[position+1:len(x)])
  • x.reverse() (or x[::-1])
  • x.sort(): what it says
  • x.count(value): number of occurrences of value
  • x.index(value): first occurrence of value
  • value in x: does value occur in x? (or logical(x.count(value)==0))
  • len(x): length
```

Note: pythonicity vs. TMTOWTDI
