introduction (week 1+)

Ben Bolker

20:55 03 January 2017

Introduction

Administrative trivia

- Instructor: Ben Bolker
    - `bolker@mcmaster.ca`: please include `1mp3` in Subject:
    - `http://www.math.mcmaster.ca/bolker`
    - HH 314 (sometimes LSB 336); office hours TBA
- TA: ??
    - `email`
- Grading:
    - midterm 20%
    - final 30%
    - in-class CodeLab assignments 15% (drop lowest 4)
    - weekly assignments 15%
    - project 20%
- Laptop policy
- Course material on Github and Avenue
- Expectations of professor and students
- Textbook (optional); also see resources
- Course content: reasonable balance among
    - nitty-gritty practical programming instruction:
      . . . I just sat down in front of a text editor, with nothing but thoughts, and ended up with a program that did exactly what I wanted it to a few hours later . . . (ankit panda
    - conceptual foundations of computing/computer science
    - context/culture of mathematical/scientific computing
    - interesting applications

Installing Python

- CodeLab: http://www.turingscraft.com/go.html
- PythonAnywhere
- Everyone must have access to a computer with Python3 installed
    - There are detailed instructions for installing Python3 on the Pragmatic Programming website.
        * Click on the 'Details' tab and scroll to the appropriate instructions for your operating system.
        * On Mac and Linux, once Python3 is installed you can run it directly from the Terminal by typing `python3`. On Windows, go to the Start menu and find Python.
- We recommend that you use PyCharm to write your programs and test things out.
    - You can find the PyCharm installer here. **The first time you run PyCharm, make sure you choose some version of python 3 from the drop-down menu**

More interesting stuff

Using computers in math and science

- math users vs. understanders vs. developers
- develop conjectures; draw pictures; write manuscripts
- mathematical proof (e.g. four-colo(u)r theorem and other examples); computer algebra
- applied math: cryptography, tomography, logistics, finance, fluid dynamics, . . .
- applied statistics: bioinformatics, Big Data/analytics, . . .
- discrete vs. continuous math

Fun!

Hello, world (always the first program you write in a new computer language)

```python
print('hello, python world!')
```

hello, python world!

Python as a fancy calculator:

```python
print(62**2*27/5+3)
```

20760.6

- *reference*: Python intro section 3.1.1

Interlude: about Python

- programming languages
    - Python: scripting; high-level; glue; general-purpose; flexible
    - contrast: *domain-specific* scripting languages (MATLAB, R, Mathematica, Maple)
    - contrast: *general-purpose* scripting languages (Perl, PHP)
    - contrast: general-purpose *compiled* languages (Java, C, C++) ("close to the metal")
- relatively modern (1990s; Python 3, 2008)
- currently the 5th most popular computer language overall (up from 8th in 2015); most popular for teaching
- well suited to mathematical/scientific/technical (NumPy; SciPy; Python in Finance)
- ex.: Sage; BioPython

the "prime walk" (from math.stackexchange.ca)

1. start at the origin, heading right, counting up from 1
2. move forward one space, counting up, until you find a prime
3. turn 90∘ clockwise
4. repeat steps 2 and 3 until you get bored

(example)

Note:

- easier to understand/modify than write from scratch
- build on existing components (*modules*)

Interfaces

- command line/console (PyCharm: `View/Tool Windows/Python Console`)
- programming editor
- integrated development environment (IDE)
- **not** MS Word! ☠

Features

- syntax highlighting

- bracket-matching

- hot-pasting

- integrated help

- integrated debugging tools

- integrated project management tools

- **most important**: maintain reproducibility; well-defined **workflows**

Assignment and types (PP §2.4)

- superficially simple
  - set aside *memory* space, create a symbol that *points to* that space
  - = is the **assignment operator** ("gets", not "equals")
  - `<variable>=<value>`
  - variable names
    * what is legal? (letters, numbers, underscores, start with a letter)
    * what is customary? convention is `variables_like_this`
    * what works well? `v` vs. `temporary_variable_for_loop`
    * same principles apply to file, directory/folder names
- variables can be of different **types**
  - built-in: integer (`int`), floating-point (`float`), complex, **Boolean** (`bool: True` or `False`),
  - *dynamic* typing
    * Python usually "does what you mean", converts types when sensible
  - (relatively) *strong* typing
    * try `print(type(x))` for different possibilities (`x=3; x=3.0; x="a"`)
    * *what happens if you try x=a?*
    * **don't be afraid to experiment!**

```
x=3
y=3.0
z="a"
q=complex(1,2)
type(x+y)  ## mixed arithmetic
type(int(x+y))  ## int(), float() convert explicitly
type(x+z)
type(q)
type(x+q)
type(True)
type(True+1) ## WAT
```

Arithmetic operators, precedence

- exponentiation (`**`)
- negation ("unary minus") (`-`)
- multiplication/division (`*`,`/`,`//`=integer division,`%`=remainder ("modulo"))
- addition/subtraction (`+`, `-` ("binary"))

Use parentheses when in doubt!

-*Puzzle:** what is `-1**2`? Why?

Logical operators (PP §5.1)

- comparison: (`==`, `!=`)
- inequalities: `>`, `<`, `>=`, `<=`,
- basic logic: (`and`, `or`, `not`)
- remember your truth tables, e.g. `not(a and b)` equals `(not a) or (not b)`

```python
a = True; b = False; c=1; d=0
a and b
not(a and not b)
a and not(b>c)
a==c  ## careful!
not(d)
not(c)
```

- **operator precedence**: same issue as order of operations in arithmetic; `not` has higher precedence than `and`, `or`. When in doubt use parentheses ...

From CodingBat:

> We have two monkeys, a and b, and the parameters `a_smile` and `b_smile` indicate if each is smiling. We are in trouble if they are both smiling or if neither of them is smiling. Return `True` if we are in trouble.

```
monkey_trouble(True, True) → True
monkey_trouble(False, False) → True
monkey_trouble(True, False) → False
```

String operations (PP chapter 4)

-reference*: Python intro section 3.1.2

- Less generally important, but fun
- `+` concatenates
- `*` replicates and concatenates
- `in` searches for a substring

```python
a = "xyz"
b = "abc"
a+1  ## error
a+b
b*3
```
Figure 1: slicing

```
(a+" ")*5
b in a
```

From CodingBat:

> Given two strings, a and b, return the result of putting them together in the order abba, e.g. "Hi"
> and "Bye" returns "HiByeByeHi".

Lists and indexing (PP chapter 8)

-reference*: Python intro section 3.1.3

Lists

- Use square brackets `[]` to set up a **list**
- Lists can contain anything but usually homogeneous
- Put other variables into lists
- Put lists into lists! ("yo dawg ...")
- `range()` makes a **range** but you can turn it into a list with `list()`
- *Set up a list that runs from 101 to 200*
- *Make a list that ...*

Indexing and slicing

-*Indexing**

- Extracting elements is called **indexing** a list
- Indexing starts from zero
- Negative indices count backward from the end of the string
  (-1 is the last element)
- Indexing a non-existent element gives an error

-*Slicing**

- Extracting (consecutive) sets of elements is called **slicing**

- Slicing non-existent element(s) gives a truncated result
- Slicing specifies *start*, *end*, *step* (or "stride")
- Leaving out a bit goes from the beginning/to the end
- Slicing works on strings too!

```
x[:]        # everything
x[a:b]      # element a (zero-indexed) to b-1
x[a:]       # a to end
x[:b]       # beginning to b
x[a:b:n]    # from a to b-1 in steps of n
```

- generate a list of odd numbers from 3 to 15
- reverse a string?

Other list operations

- Lots of things you can do with lists!
- Lists are **mutable**

```
x = [1,2,3]
y = x
y[2] = 17
print(x)
```

```
## [1, 2, 17]
```

- *operators* vs. *functions* vs. *methods* x+y vs. foo(x,y) vs. x.foo(y)
    - list *methods*
    - appending and extending:

```
x = [1,2,3]
y = [4,5]
x.append(y)
print(x)
```

```
## [1, 2, 3, [4, 5]]
```

```
x = [1,2,3] # reset x
y = [4,5]
x.extend(y)
print(x)
```

```
## [1, 2, 3, 4, 5]
```

Can use + and += as shortcut for extending:

```
x = [1,2,3]
y = [4,5]
z = x+y
print(z)
```

```
## [1, 2, 3, 4, 5]
```

- x.insert(position,value): inserts (or x=x[0:position]+[value]+x[position+1:len(x)])
- x.remove(value): removes *first* value
- x.pop(position) (or del x[position] or x=x[0:position]+x[position+1:len(x)])
- x.reverse() (or x[::-1])
- x.sort(): what it says

- `x.count(value)`: number of occurrences of `value`
- `x.index(value)`: first occurrence of `value`
- `value in x`: does `value` occur in `x`? (or `logical(x.count(value)==0)`)
- `len(x)`: length

Note: pythonicity vs. TMTOWTDI
